Slide number	Words (copied from my flashcards)
1	Hello! My name is Dill, and this is Audrey. Together, we are working on Intermittent Energy Bio Sensors.
2	We want to make it easier for hardware engineers to build and test tiny, battery-less medical sensors that don't lose data or progress when their voltage drops. We want these low-power drops to be testable, running a save-all command before the chip loses power entirely.
3	So who do we expect to use this or gain value from it? As an RTL designer, I want a dedicated "survival controller" FSM that listens for a low-voltage interrupt, so that the chip can instantly halt the main processor. As a systems engineer, I want the FPGA to automatically serialise and send all in-progress data to the FRAM, so that the chip doesn't lose progress. As an RTL designer, I also want the boot-up sequence to default to checking the FRAM first, so the system restores its saved progress. As a patient, I want this to be reliable! I don't want to do this medical test again!
4	We have access to, and plan to use, the FPGAS Vivado and Xilinx in the Photonics Labs. We have a breadboard to physically model a voltage dip, to see if the FPGA can react in time to actual data.
